

segment;

providing a source identifier code in the source identifier field, each source identifier code being uniquely associated with the message to be transmitted;

entering said destination address in the message segment of said first slot;

transmitting the slots on the network; and

controlling reassembly of slots at the destination in accordance with the source identifier code of slots received at the destination.]

[2. A method as claimed in claim 1, including the step of providing a type field in the header field of each slot, and coding into the type field a first, second or third code representing a beginning of message, a continuation of message and an end of message respectively and controlling the reassembly of received slots at the destination in accordance with the first, second and third code.]

[3. A method as claimed in claim 2, wherein the method includes the step of storing message segments associated with a single message in a buffer at the destination.]

[4. A method as claimed in claim 3, wherein if said first code is detected at the destination, the source identifier code is inputted to a comparator and if said second code associated with a subsequently received slot is detected the source identifier thereof is also inputted to the comparator to check for a match, and if a match occurs the message segment of the subsequently received slot is stored in said buffer.]

[5. A method as claimed in claim 4, wherein if said third code is detected a reassembled message in the buffer is outputted from the buffer.]

[6. A method as claimed in claim 2, including the step of coding into the type field a fourth code representing a single segment message and if said fourth code is detected in a slot received at the destination, the message segment thereof is stored in a single segment buffer.]

[7. A method as claimed in claim 5, including the step of providing multiple comparators and buffers at the destination so as to enable simultaneous receipt of a plurality of messages each having its own source identifier code, the message segments of each message being stored in a single buffer.]

[8. A method as claimed in claim 1, including the step of concurrently transmitting two or more messages from the source to the destination on the network.]

[9. Apparatus for transmitting variable length messages on a network from a source having a source address to a destination having a destination address in fixed length slots, said apparatus including:

a segmentation machine for segmenting each message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said slots including a header field which includes a source identifier field which is substantially shorter than said destination address, and a message segment,

coding means for providing a source identifier field including a source identifier code

which is uniquely associated with the message to be transmitted,

means for entering said destination address in the message segment of said first slot, and

a reassembly machine located, in use, at the destination, said reassembly machine including control means for controlling reassembly of slots in accordance with the source identifier codes of the slots.]

[10. Apparatus as claimed in claim 9, wherein said coding means provides a type field in the header field of each slot and provides a first, second or third code representing a beginning of message, a continuation of message and an end of message, respectively, and wherein the control means is responsive to said first, second and third codes.]

[11. Apparatus as claimed in claim 10, wherein said reassembly machine includes detecting means for detecting in the header fields of the received slots the presence of the third code and for detecting a match between the destination address in the slot and the destination address of the destination, and wherein if there is an address match, the detecting means copies the source identifier code into a comparator means.]

[12. Apparatus as claimed in claim 11, wherein the reassembly machine includes a plurality of said comparator means to enable concurrent receipt of slots of different messages.]

[13. Apparatus as claimed in claim 12, including means inputting the source identifier codes of received slots to said plurality of comparator means to thereby enable matching of slots

having the same source identifier codes.]

[14. Apparatus as claimed in claim 13, including a plurality of buffers for the message segments of the slots and a buffer selector circuit which selects a particular buffer for receipt of all message segments of slots having the same source identifier code whereby reassembled messages are stored in said buffers.]

The reissue patent, of which this is a divisional (i.e. RE37,494) improperly printed claims 15-39 which were not part of the application at the time of issue. Therefore every claims after claim 14 is a new claim with respect to RE37,494.

The following is a consolidation of all claims currently in this reissue application, incorporating all preliminary amendments:

sub
F1
E²

15. A method of transmitting variable length messages on a network from a source to a destination, said method comprising
segmenting each message into a plurality of fixed length slots, each of which slots includes a header field and a message segment,
providing a source identifier field in the header field of each slot, said source identifier field including a source identifier code that is uniquely associated with the message to be transmitted,
transmitting the slots on the network,
providing a type field in the header of each slot,

CONT
E²
Sub
F¹

coding into the type field, a code selected from a first code, a second code, and a third code, respectively representing a beginning of a message, a continuation of a message, and an end of a message, and
controlling the reassembly of received slots at the destination in accordance with said source identifier code, the first code, the second code, and the third code.

- [16. A method as claimed in claim 15 including the step of providing a type filed in the header field of each slot, and coding into the type field a first, second or third code representing a beginning of message, a continuation of message or an end of message respectively and controlling the reassembly of received slots at the destination in accordance with said source identifier codes and the first, second and third codes.]

Sub
F²
E³

17. A method as claimed in claim 15, further comprising

transmitting the destination address field in the message segment of the first slot of the message, and
checking a destination address field associated with the message, for a match with an address associated with the destination.

Sub
H¹

18. A method as claimed in claim 15, further comprising storing message segments associated with a single message in a buffer.

19. A method as claimed in claim 18 further comprising

providing the source identifier code to a comparator in response to detection of said first code at said destination, and

in response to detection of the second code associated with a subsequently received slot
providing the source identifier thereof to the comparator to check for a match, and
storing the message segment of the subsequently received slot in said buffer in response
to detection of a match.

20. A method as claimed in claim 19, further comprising outputting the reassembled slots in the
buffer from the buffer as a reassembled message in response to detection of said third code.

CONT
E³
21. A method as claimed in claim 15, further comprising
coding, into the type field, a fourth code representing a single segment message, and
if said fourth code is detected in a slot received at the destination, storing the message
segment thereof in a single segment buffer.

22. A method as claimed in claim 20, further comprising
providing multiple comparators and buffers at the destination so as to enable
simultaneous receipt of a plurality of messages, each having its own source identifier
code, and
storing the message segments of each message in respective buffers.

23. Apparatus for transmitting variable length messages on a network from a source to a
destination in fixed length slots, said apparatus including:
a segmentation machine for segmenting the messages into fixed length slots, each of
which includes a header field and a message segment, said segmentation machine
including coding means

for providing a source identifier field in the header of each slot, said source identifier field including a source identifier code that is uniquely associated with the message to be transmitted, and

for providing a type field in the header field of each slot, and

for providing a code selected from a first code, a second code, and a third code representing, respectively, a beginning of a message, a continuation of a message and an end of a message; and

a reassembly machine located, in use, at the destination, said reassembly machine including control means for controlling reassembly of the slots in accordance with respective source identifier codes of the slots, said control means being responsive to said source identifier code, said first code, said second code, and said third code.

- [24. Apparatus as claimed in claim 23 wherein said coding means provides a type field in the header field of each slot and provides a first, second or third code representing a beginning of message, a continuation of message or an end of message respectively, and wherein the control means is responsive to said source identifier codes and said first, second and third codes.]

25. Apparatus as claimed in claim 23 wherein the message includes a destination address field and wherein the segmentation machine is arranged to transmit the destination address field in the message segment of the first slot of the message.

26. A method of transmitting a variable-length message on a network from a source having a source address to a destination having a destination address, said method comprising:

segmenting the variable-length message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said fixed length slots including a header field that includes a source identifier field, the source identifier field being substantially shorter than said destination address, and a message segment;

providing a source identifier code in the source identifier field, said source identifier code being associated with the variable-length message;

providing a type field in the header of each slot,

coding, into the type field, a code selected from:

- a first code representing a beginning of a message,
- a second code representing a continuation of a message, and
- a third code, representing an end of a message;

transmitting the slots on the network; and

controlling reassembly of slots at the destination in accordance with the source identifier code, first code, second code, and third code of slots received at the destination.

27. Apparatus for transmitting variable-length messages on a network from a source having a source address to a destination having a destination address in fixed length slots, said apparatus including:

a segmentation machine for segmenting each message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said slots including a header field that includes a source identifier field, the source identifier field being substantially shorter than said destination address,

and a message segment;

coding means for providing the source identifier field with a source identifier code that is uniquely associated with the message to be transmitted for providing a type field in the header field of each slot, and for providing a code selected from a first code, a second code, and a third code representing, respectively, a beginning of a message, a continuation of a message and an end of a message; and
a reassembly machine located, in use, at the destination, said reassembly machine including control means for controlling reassembly of slots in accordance with respective source identifier codes, the first code, the second code, and the third code of the slots.

Please add claims 28-38 as follows (Amended from the claims added by Preliminary Amendment dated December 29, 1994 in RE37,494)

28. A method for the connection-oriented transfer of variable-length messages in fixed-length slots from a source node having a source address to a destination node having a destination address, the method comprising:

segmenting each message into a plurality of fixed-length slots including a first slot, continuing slots and a last slot, each of the slots including a header field and a message segment;
providing, in the header fields of each of the slots, a source identifier code associated with the message,
providing a type field for holding a code in the header of each slot,

Sub F3 }
coding into the type field, a code selected from a first code, a second code, and a third code, respectively representing a beginning of a message, a continuation of a message, and an end of a message,
transmitting the slots from the source node; and
controlling reassembly of the message on the basis of information in the header field of slots received at the destination node.

CONT F5 }
29. The method as claimed in claim 28 further comprising storing, in a buffer at the destination node, message segments associated with a single message.

Sub H1 }
30. The method as claimed in claim 29, further comprising
providing, to a comparator, the source identifier code of the first slot received at the destination node;
providing, to the comparator, the source identifier code of each subsequently received slot; and
storing the message segment of the subsequently received slot in the buffer in response to an occurrence of a match between the source identifier code of the first slot and the source identifier code of subsequent slots.

31. The method as claimed in claim 30, further comprising outputting a reassembled message from the buffer in response to detection of the third code.

32. The method as claimed in claim 30, further comprising

providing multiple comparators and buffers at the destination node to enable simultaneous receipt of a plurality of messages, each having its own source identifier code, and
storing message segments from each message in a separate buffer.

33. An apparatus for the connection-oriented transfer of variable-length messages in fixed-length slots from a source node, having a source address, to a destination node, having a destination address, the apparatus comprising:

a segmentation machine for segmenting each message into a plurality of fixed-length slots including a first slot, continuing slots, and a last slot, each of the fixed-length slots including a header field, and a message segment, the segmentation machine being located, in use, at the source node;

a coder for providing, in the header field of each slot,

a source identifier field for holding a source identifier code associated with the message to be transmitted, and

a type field, for holding a code selected from a first code, a second code, and a third code, respectively representing a beginning of a message, a continuation of a message, and an end of a message, and

a reassembly machine for controlling reassembly of slots into the message in accordance with information in the header field, the reassembly machine being located, in use, at the destination node.

34. The apparatus as claimed in claim 33 wherein the reassembly machine further comprises a selector for checking the third code and for providing source identifier codes to the comparator for comparison with subsequently received source identifier codes.

35. The apparatus as claimed in claim 34, wherein the reassembly machine further comprises a plurality of comparators for enabling concurrent receipt of slots associated with different messages.

36. The apparatus as claimed in claim 35, further comprising means for providing source identifier codes of received slots to the plurality of comparators, thereby enabling the comparators to match slots having the same source identifier codes.

37. The apparatus as claimed in claim 36, further comprising:
a plurality of buffers for the message segments of the slots, and
a buffer selector circuit for selecting a particular buffer for receipt of all message segments of slots having the same source identifier code.

38. The apparatus as claimed in claim 34, wherein the controller is configured to output a reassembled message from the buffer in response to detection of a third code, the reassembled message being associated with the source identifier code of the slot containing the detected third code.

Please add claims 39-70 as follows (Note: These claims were added by the 3rd Preliminary Amendment. In the 3rd Preliminary Amendment, these claims were numbered 39-71; however through inadvertence, there was no claim 43. These claims have been renumbered 39-70 to correct the numbering error.):

39. The method of claim 15 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

40. The apparatus of claim 23 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

41. A method of transmitting variable length messages on a network to a destination, said method comprising

segmenting each message into a plurality of fixed length slots, each of which slots includes a header field and a message segment,

providing a source identifier field in the header field of each slot, said source identifier field including a source identifier code that is associated with the message to be transmitted,

transmitting the slots on the network,

providing a type field in the header of each slot,

coding into the type field a code selected from a first code, a second code, and a third code, respectively representing a beginning of a message, a continuation of a message, and an end of a message, and

controlling the reassembly of received slots for delivery to the destination in accordance with said source identifier code, and any of the first code, the second code, and the third code.

42. Apparatus for transmitting variable length messages on a network from a source to a destination in fixed length slots, said apparatus including;

CNT
E\$

a segmentation machine for segmenting the messages into fixed length slots, each of which includes a header field and a message segment, said segmentation machine providing

a source identifier field in the header of each slot, said source identifier field including a source identifier code that is associated with the message to be transmitted,

a type field in the header field of each slot, and

a code selected from a first code, a second code, and a third code representing, respectively, a beginning of a message, a continuation of a message and an end of a message; and

a reassembly machine controlling reassembly of the slots in accordance with the source identifier codes of the slots, and any of said first code, said second code, and said third code.

43. A method of transmitting a variable-length message on a network to a destination, said method comprising:

segmenting the variable-length message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said fixed length slots including a header field that includes a source identifier field, and a message segment;

providing a source identifier code in the source identifier field, said source identifier code being associated with the variable-length message;

providing a type field in the header of each slot,

coding, into the type field, a code selected from:

a first code representing a beginning of a message,
a second code representing a continuation of a message, and
a third code, representing an end of a message;
transmitting the slots on the network; and
controlling reassembly of slots in accordance with the source identifier code, and any of
the first code, second code, and third code.

44. Apparatus for transmitting variable-length messages on a network to a destination in
fixed length slots, said apparatus including:

a segmentation machine segmenting each message into a plurality of fixed length
slots including a first slot, continuing slots, and a last slot, each of said slots including
a header field that includes a source identifier field,
and a message segment;
a coder providing the source identifier field with a source identifier code that is
associated with the message to be transmitted, a type field in the header field of each
slot, and a code selected from a first code, a second code, and a third code
representing, respectively, a beginning of a message, a continuation of a message and
an end of a message; and
a reassembly machine controlling reassembly of slots in accordance with the source
identifier codes, and any of the first code, the second code, and the third code of the
slots.

45. A method of transmitting variable length messages on a network to a destination having a destination address, said method including the steps of:

segmenting each message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said slots including a header field, which includes a source identifier field which is substantially shorter than said destination address, and a message segment;

providing a source identifier code in the source identifier field, each source identifier code being associated with the message to be transmitted;

entering said destination address in the message segment of said first slot;

transmitting the slots on the network; and

controlling reassembly of slots in accordance with the source identifier code.

46. Apparatus for transmitting variable length messages on a network to a destination, said apparatus including:

a segmentation machine segmenting each message into a plurality of fixed length slots including a first slot, continuing slots, and a last slot, each of said slots including a header field which includes a source identifier field and a message segment;

said segmentation machine providing a source identifier code in the source identifier field, each source identifier code being associated with the message to be transmitted, and entering said destination address in the message segment of said first slot;

a transmitter transmitting the slots on the network; and

a reassembly machine controlling reassembly of slots in accordance with the source identifier codes.

47. The method of claim 15 in which the step of coding into the type field comprises using each of the first code, the second code, and the third code in the headers of slots associated with a message.

48. The apparatus of claim 23 in which the coding means provides each of the first code, the second code, and the third code in the headers of respective slots associated with a message.

49. The method of claim 26 in which the step of coding into the type field comprises using each of the first code, the second code, and the third code in respective headers of slots associated with a message.

50. The apparatus of claim 27 in which the coding means provides each of the first code, the second code, and the third code in the headers of slots associated with a message.

51. The method of claim 28 in which the step of coding into the type field comprises using each of the first code, the second code, and the third code in respective headers of slots associated with a message.

52. The apparatus of claim 33 in which the a coder provides, in respective header fields of slots associated with a message, each of the first code, the second code, and the third code.

53. The method of claim 41 in which the step of coding into the type field comprises using each of the first code, the second code, and the third code in respective headers of slots associated with a message.

54. The apparatus of claim 42 in which the segmentation machine provides each of the first code, the second code, and the third code in respective headers of slots associated with a message.

55. The method of claim 43 in which the step of coding, into the type field, field comprises using each of the first code, the second code, and the third code in respective headers of slots associated with a message.

56. The apparatus of claim 44 in which the coder provides each of the first code, the second code, and the third code in respective headers of slots associated with a message.

57. A method for the connection-oriented transfer of variable-length messages in fixed-length slots via a source node and a destination node from a source having a source address to a destination having a destination address, the method comprising:

segmenting each message into a plurality of fixed-length slots including a first slot, continuing slots and a last slot, each of the slots including a header field and a message segment;
providing, in the header field of each of the slots, a source identifier code associated with the message,

Sub
F6

providing a type field in the header of each slot for holding a code,
coding into the type field a code for distinguishing a last slot from prior slots;
transmitting the slots from the source node; and
controlling reassembly of the message in accordance with information in the header fields
of slots received at the destination node.

58. An apparatus for the connection-oriented transfer of variable-length messages in fixed-length slots via a source node and a destination node from a source having a source address, to a destination having a destination address, the apparatus comprising:

CON
E\$

a segmentation machine for segmenting each message into a plurality of fixed-length slots including a first slot, continuing slots, and a last slot, each of the fixed-length slots including a header field, and a message segment, the segmentation machine being located, in use, at the source node;
a coder for providing, in the header field of each slot,
a source identifier field for holding a source identifier code associated with the message to be transmitted, and
a type field, for holding a code for distinguishing a last slot from previous slots; and
a reassembly machine for controlling reassembly of slots into the message in accordance with information in the header fields of slots received at the reassembly machine, the reassembly machine being located, in use, at the destination node.

59. Apparatus for transmitting variable length messages in fixed length slots on a network, via a source node and a destination node, from a source having a source address to a destination having a destination address, said apparatus including:

a segmentation machine for segmenting the messages into fixed length slots, each of which includes a header field and a message segment, said segmentation machine including a coder providing

a source identifier field in the header of each slot, said source identifier field including a source identifier code that is associated with the message to be transmitted, and

a type field in the header field of each slot, and

a code in the type field selected from a first code, a second code, and a third code representing, respectively, a beginning of a message, a continuation of a message and an end of a message; and

a reassembly machine located, in use, at the destination, said reassembly machine controlling reassembly of the slots in accordance with respective source identifier codes of the slots, said reassembly machine being responsive to said source identifier code, said first code, said second code, and said third code.

60. The method of claim 41 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

61. The apparatus of claim 42 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

62. The method of claim 43 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

63. The apparatus of claim 44 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

64. The method of claim 58 in which the source identifier code is a label which enables the logical association of all segments belonging to said message and which enables them to be reassembled into the original message.

65. The method of claim 58 in which the step of coding, into the type field, field comprises using each of the first code, the second code, and the third code in the headers of slots associated with a message.

66. The method of claim 59 in which the source identifier code is a label which enables the logical association of all fixed length slots belonging to said message and which enables them to be reassembled into the original message.

CONT
E5

Sub
H1

67. The method of claim 59 in which the step of coding into the type field comprises using each of the first code, the second code, and the third code in the headers of slots associated with a message.

68. A method as set forth in claim 41, wherein step of controlling the reassembly of received slots is accomplished using the source identifier code and at least the third code.

69. Apparatus of claim 42, wherein the reassembly machine controls the reassembly of received slots is accomplished using the source identifier code and at least the third code.

70. A method as set forth in claim 43, wherein step of controlling the reassembly of slots is accomplished using the source identifier code and at least the third code.

REMARKS

Applicants wish to thank the Examiner for the many courtesies extended during an interview with the Examiner on July 10, 2002. A copy of an Agenda of items discussed during the Interview with the Examiner is attached as an Appendix to this amendment.

The Interview

Applicants' Representatives and the Examiner discussed the items listed on than agenda, and agreed that Applicants would make of record the substance of the Interview. This portion of the Remarks will comply with that agreement.

Applicants' Representatives and the Examiner reviewed the prosecution history of the application, some history relating to the Assignee, the fact that aspects of the inventions have
